

The Data Access Layer is the part of the system that receives data from outside and passes it to the rest of the system. The most important design choice is the use of interfaces. OutputStrategy, PatientDataGenerator, and DataReader are all interfaces, which means different implementations can be swapped in without changing any other part of the system.

OutputStrategy has four concrete classes that implement it: TCP, WebSocket, File, and Console output. Each one sends data in a different way, but all follow the same interface. The generators, ECG, blood pressure, and blood saturation, all implement PatientDataGenerator and use OutputStrategy to send their output.
