

The Data Storage System is responsible for saving and retrieving patient data. The key class in it is the **DataStorage**. This class contains several **Patient** instances which, in their turn, contain arrays of **PatientRecord** instances. In other words, every patient instance has several measurements associated with him. Both relationships are composition which means that record instances do not have sense by itself, and **Patient** instances require some container.

The **DataRetriever** class performs operations related to searching patient records. This class was extracted because otherwise the **DataStorage** class would be overloaded with functionality. The **RetentionPolicy** class is responsible for automatic deleting old records. It is vital for implementation because in real life conditions storage of data requires extra efforts and considerations.

The **DataReader** interface is an abstraction of all classes capable of reading patient records into system. This information is retrieved from the original code. The dashed line from the **DataReader** class to the **DataStorage** class means that any reader should be able to communicate with storage.
