

The Patient Identification System guarantees that the incoming data is matched to the right patient. The main class is **IdentityManager** which handles everything but passes on the actual matching work to **PatientIdentifier**.

PatientIdentifier searches a database of patients by incoming ID or record. Returns a **HospitalPatient** object which contains sensitive information such as name and medical history. They are all private fields and therefore only accessible through controlled methods, which protects patient privacy. **IdentityLog** logs every match and mismatch giving you an audit trail. **MismatchException** handles the case where an incoming ID does not match any known patient, instead of ignoring the error, it is thrown and logged explicitly.
